

Project 3

Characterization of tumor neoantigens in glioblastoma patients

Data overview

Glioblastoma (GBM) is a very aggressive brain tumor for with no standard therapy after recurrence and median survival shorter than 12 months. In a recent study, GBM tumors have been characterized using whole-exome (WES) and RNA sequencing (RNA-seq) [1]. These data have been used to predict computationally patient-specific neoantigens, namely short peptides generated from the expression of mutated genes that bind to the cancer cell Human Leukocyte Antigen (HLA) molecules and can be recognized by T cells. The authors used these predicted neoantigens to design personalized anticancer vaccines for each patient to elicit T-cell antitumor response. In one patient, the vaccine elicited a CD8⁺ T-cell response towards two neoantigens generated from mutations in the SLX4 and ARHGAP35 genes.

In the Supplementary Material of this article, is available an Excel table containing the predicted neoantigens their estimated features: https://static-content.springer.com/esm/art%3A10.1038%2Fs41586-018-0792-9/MediaObjects/41586_2018_792_MOESM5_ESM.xlsx. The file contains info like the patients' identifiers, the name of the mutated gene, the HLA types, the sequence affinity in nM of the mutated and wild-type peptide, the sequence of the immunizing peptide, and the expression of the mutated gene in transcripts per millions (TPM).

Analysis to be performed

Import in R the table reporting the features of the predicted neoantigens, paying attention to the strange formatting of the first rows and header (columns might need to be re-named in R after data loading).

Only for the responder patient (patient 7), extract the information regarding the following neoantigen features or aggregated features:

n	Feature	Value for peptides recognized by T cells
1.	Affinity (IC50 in nM) of the mutant peptide	Low (i.e. peptide binds strongly to the HLA)
2.	Log-fold-change of affinity the wild-type vs. mutant peptide (WT/MUT)	Higher than zero (i.e. mutant peptide binds more strongly than wild-type peptide to the HLA)
3.	Length of the immunizing peptide	-
4.	Gene expression in TPM	High (i.e. the mutated gene is highly expressed)

For each feature, plot the value distribution across all candidate neoantigens as histograms or density plots and mark the values corresponding to the two neoantigens recognized by CD8⁺ T cells: MVNTVAGAMK (ARHGAP35 gene) and TTAATHREK (SLX4 gene)

Report

The analysis above should be described in a short report that will be evaluated and considered for the final grade. The report should:

- Contain the **code** implemented to run the analysis above, together with the **results** (as tables, plots, or just numbers reported within the text) and their **description/discussion**.
- Be at **maximum 6 pages** long.
- Be saved in a Word doc named **“Surname_Name_Project3.doc”**.
- Be sent by e-mail to Dr. Finotello not later than **June 03, 2019**, using **“RProject3_2019”** as e-mail object.
